Universal Contraindications

**NOTE:** The following list contains the standard contraindications for transplants. These contraindications apply to ALL types of transplants unless otherwise noted. There may be additional contraindications that apply to a specific type of transplant. Please refer to the “Contraindications” section in the specific type of transplant for more information.

This information was obtained from multiple sources in the peer reviewed medical literature. Unless otherwise noted, the following information was obtained from literature authored by Kasiske, Kanaan, Martin et al., Orens et al., and Mehra et al.

- **Infections**
  - Acquired Immunodeficiency Syndrome (AIDS) or certain serious and life-threatening diseases that occur in HIV-positive people. These diseases are called "AIDS-defining" conditions. When a person gets one of these illnesses, he or she is diagnosed with the advanced stage of HIV infection known as AIDS. See Appendix for a complete list of these conditions.
  - Systemic or uncontrolled infection including sepsis
- **Significant uncorrectable life-limiting medical conditions**
- **Severe end stage organ damage including but not limited to:** Severe diabetes mellitus with end organ damage, irreversible severe pulmonary disease, with FEV<sub>1</sub> < 1 L or FVC < 50%, irreversible severe hepatic disease, irreversible severe renal disease
- **Irreversible, severe brain damage**
- **Social and Psychiatric Issues** — It is expected that a patient has demonstrated adherence to all treatment plans and scheduled appointments and there is documentation of a support system and/or caregiver available to provide necessary care. A case should be referred for psychosocial evaluation and/or psychiatry consultation for guidance in any of the following circumstances:
  - Emotional instability, significant depression or other psychiatric illness that cannot be controlled that would impact ability to comply with a complex evaluation process, surgical procedure and post-transplant plan of care and/or ability to give informed consent (and does not have a representative/guardian/conservator).
  - Limited cognitive ability (memory loss, dementia, etc.) that would impact ability to comply with a complex evaluation process, surgical procedure and post-transplant plan of care and/or ability to give informed consent (and does not have a representative/guardian/conservator).
  - Lack of psychosocial support as indicated by either no identified caregiver or an uncommitted caregiver. This would include the lack of transportation to and from transplant related appointments, patient and/or caregiver is unable to adhere to the requirements of transplant related treatment plan. A care contract may be needed.
  - Lack of sufficient financial means to purchase post-transplant medications
  - History of non-adherence that has not been successfully remediated
Universal Contraindications

- Inability to give informed consent. If the patient has an authorized representative/guardian/conservator or parent in the case of a minor, that individual must understand and support the ongoing health care needs of the patient.

- Post-transplant lymphoproliferative disease (PTLD) unless no active disease demonstrated by negative positron emission tomography (PET) scan and resolved adenopathy on computed tomography (CT) and/or magnetic resonance imaging (Blaes, 2009; Khedmat, 2009)

- Limited irreversible rehabilitative potential (Bunnapradist, 2007)

References

Hematopoietic Stem Cell Transplant

General Information

- “Back-up” autologous harvesting for patients in complete remission (CR) with no evidence of marrow involvement by malignancy is appropriate. For example, bone marrow or peripheral blood progenitor cell harvesting is appropriate for patients with multiple myeloma in CR and who might be transplanted in the future. Consult benefit document.

- Donor lymphocyte infusion (DLI) following allogeneic stem cell transplant is appropriate for incomplete chimerism and disease relapse in the setting of incomplete chimerism. This is not a second stem cell transplant. (Bacigalupo, 2006)

- Repeat stem cell transplant is appropriate for primary and secondary failure to engraft and disease relapse.

- Primary failure is the failure to reach three consecutive days with a neutrophil count (absolute neutrophil count/ANC) > 500 µl (0.5 X 10^9/liter) after SCT, while secondary failure is associated with a successful SCT graft where neutrophils increase to > 500 µl (0.5 X 10^9/liter) for at least three consecutive days and subsequently decrease to a lower level until additional treatment is given to obtain engraftment. (There can be a loss of an allogeneic graft with normal blood cell counts due to autologous reconstitution. This can be confirmed with chimerism studies).

- Stem cell boost is a Hematopoietic Stem Cell Infusion (HSCI) provided to a transplant recipient to assist with hematopoietic recovery or declining donor chimerism. It is not preceded by a preparative regimen and is not considered a new transplant event. Stem cell boost is a non-standardized term and has been used interchangeably with terms such as reinfusion, support and rescue. For the purposes of this guideline, we endorse use of the term “boost” based on the recommendation of the task force set up by the American Society for Blood and Marrow Transplantation in collaboration with National Marrow Donor Program (LeMaistre, 2013) and the existence of a CPT code for the term boost (CPT 38243).

- Autologous stem cell transplant with or without a second autologous transplant (tandem transplant) is considered a standard of care for the treatment of multiple myeloma although controversy does exist particularly in the era of newer and more effective chemotherapy agents such as bortezomib, lenalidomide and thalidomide. (Blade, 2010; Harousseau, 2009; Bashey, 2008; Kumar, 2009) As the primary and salvage treatment for multiple myeloma has become increasingly successful in recent years, it is likely that, going forward, multiple factors will need to be considered prior to making decisions regarding the use of transplantation procedures; e.g., risk stratification, age, comorbidities, etc. and that the role of transplantation may decrease for certain subgroups.

- During a tandem transplant, a patient receives two sequential courses of high-dose chemotherapy with stem cell transplant. Peripheral blood hematopoietic stem cells (HSCs) are collected either during recovery of a cycle of induction chemotherapy or after filgrastim mobilization. The patient receives a second preparative regimen, along with hematopoietic progenitor cells (HPCs) collected during the initial mobilization. Both transplantations are planned in advance and typically are performed a few weeks to a few months apart. (LeMaistre, 2013)
• Tandem stem cell transplants require review by the Medical Director except for the following conditions: multiple myeloma, testicular germ cell tumors or neuroblastoma, pediatric brain tumors, and other conditions as part of an IRB approved clinical trial.

• Third stem cell transplants require Medical Director Review.
  – If part of a sequence of high-dose chemotherapy followed by rescue stem cell infusion as is the case with some neuroblastoma, medulloblastoma and testicular germ cell tumor protocols, the entire course may be approved initially

• Stem cell source and preparative regimens are at the discretion of the treating physician.
  – Single unit umbilical cord blood stem cell transplants are standard of care for children in many programs. Children > 45 kg who receive a single cord blood unit may experience prolonged time to engraftment and other post-transplant complications; therefore, a calculation of $2.5 \times 10^7$ nucleated cells per kilogram may improve response. (de Lima, 2006)
  – If a matched related donor is not available AND no donors have been identified through the National Marrow Donor Program (NMDP) OR there is urgency to transplant sooner than would be expected to be possible through a conventional search and harvest of an unrelated donor through the NMDP, the use of stem cells derived from umbilical cord blood or haploidentical donors cells can be authorized under certain circumstances.

• The stem cell transplant expert panels have confirmed that the treatment of any pediatric patient under a Children's Oncology Group (COG) protocol should be considered Standard of Care.

• Patients who have undergone stem cell transplant have altered immune systems post-transplant. In the case of allogeneic stem cell transplant, the immune system may never fully recover. These patients have unique care needs in the post-transplant period and will require lifelong follow-up and management. (Optum Expert Panel, 2015)

• Chimeric Antigen Receptor Therapy and/or the use of T-cells/natural killer cell protocols provide treatment of the underlying disease and are not considered to be a transplant procedure. Patients receive immune-depleting chemotherapy prior to infusion. Requests for this therapy have been received for such diseases as ALL or neuroblastoma. As it is not a transplant, the review of such requests should be completed by whoever authorizes the medical benefits for the patient and to determine if benefits for participation in a clinical trial exist. (Kalos, 2011)

• The definition of multiple myeloma has been updated. (Rajkumar et al.) As such the diagnoses of frank myeloma, smoldering myeloma and MGUS have changed and can affect indications for treatment. (See Appendix.)

• In an effort to improve outcomes of blood and marrow transplantation, the use of maintenance therapy has received significant attention over the past few years. While it is likely that post-transplant treatment will continue to evolve, there have been a number of maintenance regimens that have demonstrated reasonable effectiveness to merit their coverage when the treating team feels it to be indicated. Covered maintenance therapy regimens include:
  – Rituximab maintenance after autologous transplant for relapsed follicular lymphoma showed a benefit in terms of progression free survival (PFS) though no benefit in overall survival (OS). (Pettengell, 2013)
Rituximab maintenance following autologous transplant in patients with previously untreated Mantle cell lymphoma resulted in an improved PFS but not OS. (Dietrich, 2001)

Brentuximab vedotin after autologous stem cell transplantation for patients with Hodgkin’s lymphoma at high risk of relapse or progression showed improved PFS in the AETHERA trial. (Moskowitz et al.) It is reasonable to use in patients who fit into the well-defined criteria of high risk outlined in the Moskowitz et al. paper: primary refractory Hodgkin’s lymphoma, initial remission duration of less than 1-year, and presence of extranodal or advanced-stage disease at time of relapse. Two important risk factors before autologous stem cell transplantation are lack of chemosensitivity to pre autologous stem cell transplantation salvage chemotherapy, and residual disease at the time of high-dose therapy, defined by CT or PET.

Immunomodulatory drugs such as thalidomide or lenalidomide, unless a contraindication exists, as recommended by the American Society for Blood and Marrow Transplantation for multiple myeloma. (Shah, 2015)

There is insufficient evidence to support other agents used as maintenance therapy in malignancies other than as described above. Requests for coverage for any other maintenance regimens should be referred to a Medical Director.

Traditionally the treatment of veno-occlusive disease (VOD) has been supportive and the outcomes poor. In March 2016, FDA gave approval to the new drug defibrotide for the treatment of active VOD. At the present time there is not an approved indication for its use in a prophylactic manner which is commonly done overseas in Europe.

Defibrotide is covered for the treatment of adult and pediatric patients with active hepatic VOD with renal or pulmonary dysfunction following hematopoietic stem cell transplant.

Defibrotide is not covered for the prevention of VOD

**Indications**

If an indication is listed as “Not standard of care”, the requested service may be covered if there is a state mandate, the member has a cancer clinical trial benefit, can be covered under the CRS program, if there is a life threatening illness clause in the benefit plan, etc. and all provisions of the applicable benefit(s) have been met.

CHECK FOR STATE MANDATES AND THE MEMBER’S BENEFIT PLAN TO DETERMINE ELIGIBILITY.

- ✓ = COVERED INDICATION
- N = NOT A COVERED INDICATION
- □ = If nothing is indicated, this generally means that this is not considered an indication for stem cell transplant of the type requested and we do not expect to see requests for authorization for this particular type of stem cell transplant for this indication. Any requests for stem cell transplant for one of these indications will be referred to the Medical Director for review.

Disease/Indication | Auto | Allo | Comment
---|---|---|---
**Cardiac Conditions**

Heart Disease | N | N | Not standard of care. It would only be considered for approval under a clinical trial if the member’s benefit plan supports participation in a clinical trial.

**Additional Condition/Disease Indications**

Refer to section titled: | ✓ | | The reference sheet includes a list of rare and unusual conditions where allogeneic transplant may be indicated. If there is a condition found within this reference that is not included above, refer to Medical Director.

**Organ-specific Contraindications**

*Please review the universal Contraindications found at the beginning of the Guidelines. These apply to all transplants unless otherwise noted below. Additional contraindications that are specific to a particular type of transplant are noted below. When a Contraindication is present the transplant will not be approved. Refer to the Medical Director.*

- None

**Special Considerations**

Additional consultation and/or evaluation may be indicated in these situations. Refer to Medical Director if questions remain.

- Cord blood transplants in adults
  - When stem cells are not available from a standard donor source, there may be no reasonable alternative to the use of cord blood units in adults. The available literature supports this approach. In this situation umbilical cord blood SCTs may be approved as standard of care. (Brunstein et al.)
    - If participation in a clinical trial is requested, all clinical trial authorization rules will apply.
- Haploidentical stem cell transplants are occurring more frequently due to advances in immunosuppression and the ease of acquiring a donor.
  - Haploidentical SCT can be approved as an acceptable form of treatment at a center that is FACT-accredited for allogeneic stem cell therapy. (Klingebiel, 2010)
• **Multiple Myeloma**

Allogeneic stem cell transplant for multiple myeloma is controversial either as a single allogeneic transplant as initial therapy with curative intent or as the second stage of a planned tandem transplant proceeded by an autologous transplant. The following recommendations are consistent with the evolving practice and recognize the expertise of treating physicians within network programs. The recommendations may change as additional experience is gained with the newer disease modifying agents for the treatment of myeloma and as more experience is gained with reduced intensity allogeneic stem cell transplant for this disease.

**Note:** Refer all requests for allogeneic stem cell transplant in multiple myeloma to Medical Director for review.

- Allogeneic stem cell transplant may be appropriate therapy under the following circumstances

  • Initial therapy in newly diagnosed patients with high-risk disease and in otherwise good health
    - High risk myeloma has been defined by the International Myeloma Working Group (IMWG) based on cytogenics [Presence of at least one of the following: del(17p), t(4;14) or t(14;16) determined by FISH] and the Mayo Clinic classification adds hypoploidy and t(14;20) to the IMWG definition. Regardless of the source of definition, the requestor should present evidence of sufficient factors that cause the case to be considered high risk.
  
  • Early relapse (less than 24 months) after primary therapy that included an autologous stem cell transplant or with high-risk features (i.e., cytogenetics, extramedullary disease, plasma cell leukemia, or high lactate dehydrogenase) provided that they respond favorably to salvage therapy. (Giralt, 2015)
  
  • Reduced intensity matched related donor (MRD) and matched unrelated donor (MUD) allogeneic SCT as the second transplant of a planned tandem transplant. (Bruno, 2009; Rotta, 2009)
    - The role and choice of maintenance therapy after hematopoietic stem cell transplant is in evolution. It appears to have a role in treatment of residual or relapsed disease or as part of a clinical study to prevent relapse. (Shah, 2015) It can be covered in these situations but any request should be referred to the Medical Director for review.

• HIV infection
  - Patients should have a formal infectious disease consult indicating adequate treatment and proper assessment of risks related to this transplant

• Persisting CNS involvement by malignancy except for primary CNS tumors such as those referenced under brain tumor indications.
  - Refer to Medical Director

• Refer to requesting program Patient Selection Criteria for age specific criteria.
  - If outside the program’s patient selection criteria, refer to Medical Director

• Serum creatinine < 2.5 mg/dl (≤ 1.5 mg/dl in children) or GFR > 50 ml/min.
– Serum creatinine may be higher in patients with multiple myeloma or other plasma cell dyscrasias. Patients with multiple myeloma with reduced renal function are not prohibited from undergoing autologous BMT when the decreased renal function is related to the multiple myeloma (myeloma kidney). This includes patients on hemodialysis with no other contraindications.

• Pediatric patients should have a Lansky score > 50. Adult patients should have a Karnofsky score > 70. If these criteria not met, refer to Medical Director.

• Active untreated or untreatable malignancy in patients undergoing stem cell transplantation for non-malignant indications
  – Refer to Medical Director
Hematopoietic Stem Cell Transplant —
Timing for Stem Cell Transplant Consultation

RECOMMENDED TIMING FOR STEM CELL TRANSPLANTATION CONSULTATION (National Marrow Donor Program®/Be The Match® and the American Society for Blood and Marrow Transplantation)

These guidelines for transplant consultation were developed jointly, and updated for 2015, by the National Marrow Donor Program (NMDP) and the American Society for Blood and Marrow Transplantation (ASBMT). They are based on current clinical practice and the medical literature, including comprehensive evidence based reviews. One critical factor in the outcome of hematopoietic cell transplantation is the appropriate planning and timing of the transplant. The intent of these guidelines is to identify patients at risk of disease progression and, therefore, which patients should be evaluated for transplantation.

While transplant may be immediately indicated for some patients with these factors, it may not be for all patients. The consultation helps ensure there are plans in place for the patient to move quickly to transplant, if needed, before disease progresses or complications develop. If allogeneic transplant is a possibility, it helps provide adequate time for an unrelated donor or cord blood search.

ADULT LEUKEMIAS AND MYELODYSPLASIA

Acute Myelogenous Leukemia (AML)

- High resolution HLA typing is recommended at diagnosis for all patients
- Early after initial diagnosis, all AML patients including:
  - CR1—except favorable risk AML (defined as: t (16;16); inv 16; t (8;21); t (15;17); normal cytogenetics with NPM1 or biallelic CEBPA mutation and without FLT3-ITD)
  - Antecedent hematological disease (e.g., myelodysplastic syndrome (MDS))
  - Treatment-related leukemia
  - Primary induction failure or relapse
  - Presence of minimal residual disease after initial or subsequent therapy
  - CR2 and beyond, if not previously evaluated

Acute Lymphoblastic Leukemia (ALL)

- High resolution HLA typing is recommended at diagnosis for all patients
- Early after initial diagnosis, all ALL patients including:
  - CR1
  - Primary induction failure or relapse
– Presence of minimal residual disease after initial or subsequent therapy
– CR2 and beyond, if not previously evaluated

Myelodysplastic Syndromes (MDS)
• Any intermediate or high IPSS score
• Any MDS with poor prognostic features, including:
  – Treatment-related MDS
  – Refractory cytopenias
  – Adverse cytogenetics
  – Transfusion dependence

Chronic Myelogenous Leukemia (CML)
• Inadequate hematologic or cytogenetic response to tyrosine kinase inhibitor (TKI) therapies
• Disease progression
• Intolerance to TKI therapies
• Accelerated phase
• Blast crisis (myeloid or lymphoid)

Chronic Lymphocytic Leukemia (CLL)
• High-risk cytogenetics or molecular features (e.g., del(11q) or del(17p); ZAP70, CD38 positivity; unmutated Ig VH mutational status)
• Short initial remission
• Poor initial response
• Fludarabine-resistant
• Richter’s transformation

PEDIATRIC ACUTE LEUKEMIAS

Acute Myelogenous Leukemia (AML)
• High resolution HLA typing is recommended at diagnosis for all patients
• Early after initial diagnosis, all AML patients including:
  – CR1—except favorable risk AML (defined as: t (16;16); inv 16; t (8;21); t (15;17); normal cytogenetics with PM1 or biallelic CEBPA mutation and without FLT3-ITD)
  – Primary induction failure or relapse
– Monosomy 5 or 7
– Age <2 years at diagnosis
– Treatment-related leukemia
– Presence of minimal residual disease after initial or subsequent therapy
– CR2 and beyond, if not previously evaluated

**Acute Lymphoblastic Leukemia (ALL)**

- Infant at diagnosis
- High Risk CR1 including:
  - Philadelphia chromosome positive
  - WBC >100,000 at diagnosis
  - 11q23 rearrangement
- Mature B-cell phenotype (Burkitt’s lymphoma)
- Primary induction failure or relapse
- Presence of minimal residual disease after initial or subsequent therapy
- CR2 and beyond, if not previously evaluated

**LYMPHOMAS**

**Non-Hodgkin Lymphoma**

- Follicular
- Poor response to initial treatment
- Initial remission duration <12 months
- First relapse
- Transformation to diffuse large B-cell lymphoma

**Diffuse Large B-Cell or High-Grade Lymphoma**

- At first or subsequent relapse
- CR1 for patients with high or high-intermediate IPI risk
- No CR with initial treatment
- Second or subsequent remission

**Mantle Cell**

- After initiation of therapy
Other High Risk Lymphomas
- After initiation of therapy

Hodgkin Lymphoma
- Primary induction failure or relapse
- Second or subsequent remission

Multiple Myeloma
- All patients after initiation of therapy
- At first progression

OTHER MALIGNANT DISEASES

Germ cell tumors
- Short initial remission
- Poor initial response

Myeloproliferative Disorders (including BCR-ABL–negative myeloproliferative neoplasms, myelofibrosis and later stages of polycythemia vera and essential thrombocytosis)
- Intermediate or high-risk disease including:
  - High-risk cytogenetics
  - Poor initial response or at progression

Neuroblastoma
- Short initial remission
- Poor initial response or at progression

NON-MALIGNANT DISORDERS

Immune Deficiency Diseases (including Severe Combined Immunodeficiency syndromes, Wiskott-Aldrich syndrome, Omenn syndrome, X-linked lymphoproliferative syndrome, Kostmann syndrome)
- At diagnosis
Inherited Metabolic Disorders (including Hurler’s syndrome, adrenoleukodystrophy, and others)

- At diagnosis

HEMAGLOBINOPATHIES

Transfusion-Dependent Thalassemias

- At diagnosis

Sickle Cell Disease

- With aggressive course (end-organ complications, frequent pain crises)

Hemophagocytic Lymphohistiocytosis (HLH)

- At diagnosis

Severe Aplastic Anemia and other marrow failure syndromes (including Fanconi anemia, Diamond-Blackfan anemia, and others)

- At diagnosis

Appendix

AIDS-defining Conditions

Certain serious and life-threatening diseases that occur in HIV-positive people are called "AIDS-defining" conditions. When a person gets one of these illnesses, he or she is diagnosed with the advanced stage of HIV infection known as AIDS.

The Centers for Disease Control and Prevention (CDC) has developed a list of these conditions (see below). No single patient is likely to have all of these problems. Some of the conditions are rare.

- Bacterial infections, multiple or recurrent*
- Candidiasis of bronchi, trachea, or lungs
- Candidiasis of esophagus†
- Cervical cancer, invasive.§
- Coccidioidomycosis, disseminated or extrapulmonary
- Cryptococcosis, extrapulmonary
- Cryptosporidiosis, chronic intestinal (>1 month's duration)
- Cytomegalovirus disease (other than liver, spleen, or nodes), onset at age >1 month
- Cytomegalovirus retinitis (with loss of vision)†
- Encephalopathy, HIV related
- Herpes simplex: chronic ulcers (>1 month's duration) or bronchitis, pneumonitis, or esophagitis (onset at age >1 month)
- Histoplasmosis, disseminated or extrapulmonary
- Isosporiasis, chronic intestinal (>1 month's duration)
- Kaposi sarcoma†
- Lymphoid interstitial pneumonia or pulmonary lymphoid hyperplasia complex*†
- Lymphoma, Burkitt (or equivalent term)
- Lymphoma, immunoblastic (or equivalent term)
- Lymphoma, primary, of brain
- *Mycobacterium avium* complex or *Mycobacterium kansasii*, disseminated or extrapulmonary†
- *Mycobacterium tuberculosis* of any site, pulmonary,†‡ disseminated,† or extrapulmonary†
- *Mycobacterium*, other species or unidentified species, disseminated‡ or extrapulmonary†
- *Pneumocystis jiroveci* pneumonia†
- Pneumonia, recurrent†‡
Appendix

- Progressive multifocal leukoencephalopathy
- *Salmonella* septicemia, recurrent
- Toxoplasmosis of brain, onset at age >1 month†
- Wasting syndrome attributed to HIV

* Only among children aged <13 years. (CDC. 1994 Revised classification system for human immunodeficiency virus infection in children less than 13 years of age. MMWR 1994;43[No. RR-12].)

† Condition that might be diagnosed presumptively.

§ Only among adults and adolescents aged ≥13 years. (CDC. 1993 Revised classification system for HIV infection and expanded surveillance case definition for AIDS among adolescents and adults. MMWR 1992;41[No. RR-17].)

Clinical, Cytogenetic and Mutational Risk Stratification for AML

Favorable risk:
- Cytogenetics
  - t(8;21)
  - inv(16) or t(16;16)
- Mutations
  - Kit

Intermediate risk (one or more of the following)
- Cytogenetics
  - Normal
  - +8
- Mutations
  - Flt3 ITD-positive
  - Mutant TET2, MLL-PTD, DNMT3A, ASXL1, PHF6

Unfavorable (high) risk (one or more of the following):
- Cytogenetics
  - -5/-7
  - 11q23, 20q
  - 3 or more
- Clinical features:
  - CR2 and beyond
  - Age > 70
  - Refractory to induction chemotherapy
  - Persistence of minimal residual disease following induction

The Dynamic International Prognostic Scoring System (DIPSS) for Primary Myelofibrosis (PMF)

The DIPSS for PMF uses five risk factors to predict survival. Values for score calculation are as follows:

<table>
<thead>
<tr>
<th>Risk Factors</th>
<th>Point Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age &gt; 65</td>
<td>1</td>
</tr>
<tr>
<td>Hemoglobin level &lt; 10 g/dl</td>
<td>2</td>
</tr>
<tr>
<td>White blood cell count (WBC) &gt; 25 x 10^9/L</td>
<td>1</td>
</tr>
<tr>
<td>Peripheral blood blasts ≥ 1%</td>
<td>1</td>
</tr>
<tr>
<td>Presence of constitutional symptoms</td>
<td>1</td>
</tr>
</tbody>
</table>

Risk categories: Low (score 0), intermediate-1 (score 1 or 2), intermediate-2 (score 3-4), high (score 5-6).

Complete Remission and Partial Remission Highlights from Revised Response Criteria for Malignant Lymphoma (Cheson et al.)

Complete Remission (CR): Disappearance of all evidence of disease.

Nodal masses
- FDG-avid or PET positive prior to therapy: mass of any size permitted if PET negative
- Variably FDG-avid or PET negative: regression to normal size on CT

Spleen, Liver
- Not palpable, nodules disappeared

Bone marrow
- Infiltrate cleared on repeat biopsy; if indeterminate by morphology, immunohistochemistry should be negative

Partial Remission (PR): Regression of measurable disease and no new sites.

Nodal masses
- Greater than 50% decrease in sum of the products of diameters (SPD) of up to 6 largest dominant masses; no increase in size of other nodes
  - FDG-avid or PET positive prior to therapy; one or more PET positive at previously involved site
  - Variably FDG-avid or PET negative; regression on CT
  NOTE: In the absence of adequate size measurements one can use a greater than 50% decrease in the Standardized Uptake Value (SUV) to document PR.

Spleen, Liver
- Greater than 50% decrease in SPD of nodules (for single nodule in greatest transverse diameter); no increase in size of liver or spleen.

Bone marrow
- Irrelevant if positive prior to therapy; cell type should be specified.

Hematopoietic Stem Cell Transplant Reference Sheet

The following is a list of rare and unusual conditions where allogeneic transplant may be indicated. The list was reviewed and accepted by the 2016 Optum Hematopoietic Stem Cell Transplant Expert Panel. If there is a condition found on this list that is not included in the “Indications” section above, refer to Medical Director.

1. Lymphocyte Immunodeficiencies (many of these fall under ‘severe combined immunodeficiency’ classification)
   - Adenosine deaminase deficiency
   - Artemis deficiency
   - Calcium channel deficiency
   - Cernunnos-XLF immunodeficiency
   - CHARGE syndrome with immune deficiency
   - Common gamma chain deficiency
   - Deficiencies in CD 45, CD3, CD8
   - DiGeorge syndrome
   - DNA ligase IV
   - Interleukin-7 receptor alpha deficiency
   - Janus-associated kinase 3 (JAK3) deficiency
   - Major histocompatibility class II deficiency
   - Purine nucleoside phosphorylase deficiency
   - Recombinase-activating gene (RAG) 1/2 deficiency
   - Reticular dysgenesis
   - Winged helix deficiency
   - Zeta-chain-associated protein-70 (ZAP-70) deficiency

2. Phagocytic Deficiencies
   - Chediak-Higashi syndrome
   - Griscelli syndrome, type 2
   - Interferon-gamma receptor deficiencies
   - Leukocyte adhesion deficiency
   - Shwachman-Diamond syndrome*
   *may be considered as marrow failure syndrome rather than immunodeficiency
3. Other Immunodeficiencies

- Autoimmune lymphoproliferative syndrome
- Cartilage hair hypoplasia
- CD25 deficiency
- Familial hemophagocytic lymphohistiocytosis
- Hyper IgD and IgE syndromes
- ICF syndrome
- IPEX syndrome
- NEMO deficiency
- NF-κB inhibitor, alpha (IκB-alpha)

Updated Criteria for Diagnosis of Multiple Myeloma (Rajkumar, 2014)

MULTIPLE MYELOMA

DIAGNOSTIC CRITERIA: ALL 3 REQUIRED

- Monoclonal plasma cells in the bone marrow > 10% and/or presence of a biopsy-proven plasmacytoma
- Monoclonal protein present in the serum and/or urine *
- Myeloma-related organ dysfunction (1 or more) **

Traditional CRAB Criteria:

[C] Calcium elevation in the blood S. Calcium >10.5 mg/l or upper limit of normal
[R] Renal insufficiency S. Creatinine > 2 mg/dl
[A] Anemia Hemoglobin < 10 g/dl or 2 g < normal
[B] Lytic bone lesions or osteoporosis *

NOTE: THESE CRITERIA IDENTIFY STAGE IB and STAGES II and III A/B MYELOMA BY DURIE/SALMON STAGE. Stage IA becomes smoldering or indolent myeloma.

* If no monoclonal protein is detected (non-secretory disease), then > 30 % monoclonal bone marrow plasma cells and/or a biopsy-proven plasmacytoma required.

** The revised International Myeloma Working Group (IMWG) criteria will allow, in addition to the classic CRAB features, the following three markers as "myeloma defining events" (MDEs):

- Sixty percent or greater clonal plasma cells on bone marrow examination
- Serum involved/uninvolved free light chain ratio of 100 or greater, provided the absolute level of the involved free light chain is at least 100 mg/l (a patient’s “involved” free light chain – either kappa or lambda – is the one that is above the normal reference range; the uninvolved light chain is the one that typically is in, or below, the normal range)
- More than one focal lesion on MRI that is at least 5 mm or greater in size

The presence of at least one of these markers will be considered sufficient for a diagnosis of multiple myeloma, regardless of the presence or absence of symptoms or CRAB features. Each of these markers has been shown in two or more independent studies to be associated with an approximately 80 % or higher risk of developing myeloma-related organ damage within two years.

In addition, the IMWG criteria allow the use of CT and PET-CT for detecting osteolytic bone lesions in order to make the diagnosis of myeloma. In patients with equivocal findings on MRI, CT, and/or PET-CT, the IMWG recommends follow-up imaging. The use of modern imaging methods at diagnosis and follow-up will enable the diagnosis of myeloma to be made before serious bone damage, such as pathologic fractures, can develop.
MGUS: MONOCLONAL GAMMOPATHY of UNDETERMINED SIGNIFICANCE

DIAGNOSTIC CRITERIA: ALL 3 REQUIRED

- Serum monoclonal protein and/or urine monoclonal protein level low*
- Monoclonal bone marrow plasma cells < 10%
- Normal serum calcium, hemoglobin level and serum creatinine

* Low is defined as:
  - Serum IgG < 3.5 g/dl
  - Serum IgA < 2.0 g/dl

No bone lesions on full skeletal x-ray survey and/or other imaging if performed
No clinical or laboratory features of amyloidosis or light chain deposition disease
Urine monoclonal kappa or lambda < 1.0 g/24 hours
The definition of MGUS has not changed. However, a new entity termed light chain MGUS has been defined.

SMOLDERING OR INDOLENT MYELOMA

DIAGNOSTIC CRITERIA: ALL 3 REQUIRED

- Monoclonal protein present in the serum and/or urine
- Monoclonal plasma cells present in the bone marrow and/or a tissue biopsy
- Not meeting criteria for MGUS, multiple myeloma, or solitary plasmacytoma of bone

NOTE: THESE CRITERIA IDENTIFY STAGE IA MYELOMA BY DURIE/SALMON STAGE.

The diagnosis of smoldering myeloma will now have an upper limit of 60% for the percentage of clonal plasma cells in the marrow. Patients considered to have smoldering myeloma should not have any myeloma defining events or amyloidosis.

A new kind of smoldering multiple myeloma, termed light chain smoldering multiple myeloma, has been recently described in a study conducted at the Mayo Clinic, and the specific monoclonal protein level required for this diagnosis has also been added.

The following are approved changes incorporated into the revision numbers indicated below.
